EXCEPT AS PROVIDED IN INTEL'S TERMS AND CONDITIONS OF SALE FOR SUCH PRODUCTS, INTEL ASSUMES NO LIABILITY WHATSOEVER AND INTEL DISCLAIMS ANY EXPRESS OR IMPLIED WARRANTY, RELATING TO SALE AND/OR USE OF INTEL PRODUCTS INCLUDING LIABILITY OR WARRANTIES RELATING TO FITNESS FOR A PARTICULAR PURPOSE, MERCHANTABILITY, OR INFRINGEMENT OF ANY PATENT, COPYRIGHT OR OTHER INTELLECTUAL PROPERTY RIGHT.

A "Mission Critical Application" is any application in which failure of the Intel Product could result, directly or indirectly, in personal injury or death. SHOULD YOU PURCHASE OR USE INTEL'S PRODUCTS FOR ANY SUCH MISSION CRITICAL APPLICATION, YOU SHALL INDEMNIFY AND HOLD INTEL AND ITS SUBSIDIARIES, SUBCONTRACTORS AND AFFILIATES, AND THE DIRECTORS, OFFICERS, AND EMPLOYEES OF EACH, HARMLESS AGAINST ALL CLAIMS COSTS, DAMAGES, AND EXPENSES AND REASONABLE ATTORNEYS' FEES ARISING OUT OF, DIRECTLY OR INDIRECTLY, ANY CLAIM OF PRODUCT LIABILITY, PERSONAL INJURY, OR DEATH ARISING IN ANY WAY OUT OF SUCH MISSION CRITICAL APPLICATION, WHETHER OR NOT INTEL OR ITS SUBCONTRACTOR WAS NEGLIGENT IN THE DESIGN, MANUFACTURE, OR WARNING OF THE INTEL PRODUCT OR ANY OF ITS PARTS.

Intel may make changes to specifications and product descriptions at any time, without notice. Designers must not rely on the absence or characteristics of any features or instructions marked "reserved" or "undefined". Intel reserves these for future definition and shall have no responsibility whatsoever for conflicts or incompatibilities arising from future changes to them. The information here is subject to change without notice. Do not finalize a design with this information.

The products described in this document may contain design defects or errors known as errata which may cause the product to deviate from published specifications. Current characterized errata are available on request.

Contact your local Intel sales office or your distributor to obtain the latest specifications and before placing your product order.

Copies of documents which have an order number and are referenced in this document, or other Intel literature, may be obtained by calling 1-800-548-4725, or go to: http://www.intel.com/design/literature.htm

Revision History

Date	Revision	Description	
February 2014	1.0	Initial public release.	

§

1.1 Purpose

The purpose of this document is to describe the steps required to integrate the FSP into a boot loader solution.

1.2 Intelligent Systems and Embedded Ecosystem Overview

Contrasting the PC ecosystem where hardware and software architecture are following a set of industry standards, the Intelligent Systems (embedded) ecosystem often does not adhere to the same industry standards. Design engineers for Intelligent Systems and Embedded Systems frequently combine components from different vendors with a set of very distinct functions in mind.

The criteria for picking the right boot loader are often based on boot speed and code size. The boot loader also frequently has close ties with the OS from a functionality perspective. To give freedom to customers to choose the best boot loader for their applications, Intel provides the Firmware Support Package (FSP) to satisfy the needs of design engineers.

1.3 Intended Audience

This document is targeted at all platform and system developers who need to consume FSP binaries in their boot loader solutions. This includes, but is not limited to: system BIOS developer, boot loader developer, system integrators, as well as end users.

1.4 Related Documents

- Platform Initialization (PI) Specification located at <u>http://www.uefi.org/specifications/</u>.
- Intel[®] Firmware Support Package: Introduction Guide available at <u>www.intel.com/fsp</u>
- Binary Configuration Tool for Intel[®] Firmware Support Package available at <u>www.intel.com/fsp</u>

1.5 Conventions

To illustrate some of the points better, the document will use code snippets. The code snippets follow **the GNU C Compiler** and **GNU Assembler** syntax.

1.6 Acronyms and Terminology

BSP	Boot Strap Processor
BWG	BIOS Writer's Guide
CRB	Customer Reference Board
FSP	Firmware Support Package
FSP API	Firmware Support Package Interface
FWG	Firmware Writer's Guide
IVI	In Vehicle Infotainment
NBSP	Node BSP
RSM	Resume to OS from SMM
SBSP	System BSP
SMI	System Management Interrupt
SMM	System Management Mode
TSEG	Memory Reserved at the Top of Memory to be used as SMRAM

2 FSP Overview

2.1 Design Philosophy

Intel recognizes that it holds the key programming information that is crucial for initializing Intel silicon. After Intel provides the key information, most experienced firmware engineers can make the rest of the system work by studying specifications, porting guides, and reference code.

2.2 Technical Overview

The Intel[®] Firmware Support Package (FSP) provides chipset and processor initialization in a format that can easily be incorporated into many existing boot loaders.

The FSP will perform all the necessary initialization steps as documented in the BWG including initialization of the CPU, memory controller, chipset and certain bus interfaces, if necessary.

FSP is not a stand-alone boot loader; therefore it needs to be integrated into a host boot loader to carry out other boot loader functions, such as: initializing non-Intel components, conducting bus enumeration, and discovering devices in the system and all industry standard initialization.

3 FSP Integration

The FSP binary can be integrated easily into many different boot loaders, such as Coreboot, etc. and also into embedded OS directly.

Below are some required steps for the integration:

Customizing

The static FSP configuration parameters are part of the FSP binary and can be customized by external tools that will be provided by Intel.

Rebasing

The FSP is not Position Independent Code (PIC) and the whole FSP has to be rebased if it is placed at a location which is different from the preferred address specified during building the FSP.

• Placing

Once the FSP binary is ready for integration, the boot loader build process needs to be modified to place this FSP binary at the specific rebasing location identified above.

• Interfacing

The boot loader needs to add code to setup the operating environment for the FSP, call the FSP with the correct parameters and parse the FSP output to retrieve the necessary information returned by the FSP.

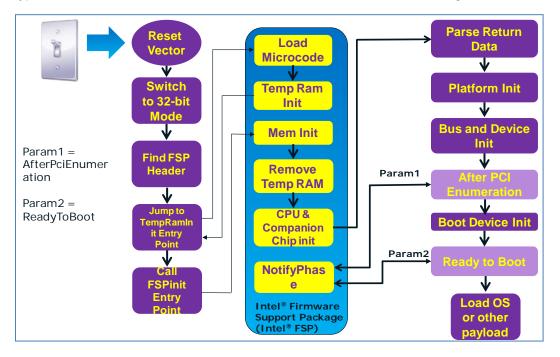

3.1 Assumptions Used in this Document

Because the 3rd Generation Intel[®] Core[™] Processors with Mobile Intel[®] HM76/QM77 Express Chipsets FSP is built with a preferred base address of 0xFFF80000, the FSP binary is assumed to be placed at the same address as part of the boot loader build.

4 **Boot Flow**

The figure below shows the boot flow from the reset vector to the OS handoff for a typical boot loader. The APIs are described in more detail in the following sections.

5 **FSP Binary Format**

The FSP is distributed in binary format. The FSP binary contains an FSP specific **FSP_INFORMATION_HEADER** structure, the initialization code/data needed by the Intel Silicon supported by the FSP and a configuration region that allows the boot loader developer to customize some of the settings through a tool provided by Intel.

5.1 **FSP Header**

The FSP header conveys the information required by the boot loader to interface with the FSP binary such as providing the addresses for the entry points, configuration region address, etc.

Byte Offset	Size in Bytes	Field	Description
0	4	Signature	'FSPH'. Signature for the FSP Information Header.
4	4	HeaderLength	Length of the header
8	3	Reserved	Reserved
11	1	HeaderRevision	Revision of the header.
12	4	ImageRevision	Revision of the FSP Binary. The ImageRevision can be decoded as follows 07 - Minor Version 815 - Major Version 1631 - Reserved
16	8	Image Id	8-byte signature string that will help match the FSP Binary to a supported hardware configuration.
24	4	ImageSize	Size of the entire FSP Binary.
28	4	ImageBase	FSP binary preferred base address. If the FSP binary will be located at the address different from the preferred address, the rebasing tool is required to relocate the base before the FSP binary integration. For the 3rd Generation Intel [®] Core [™] Processors with Mobile Intel [®] HM76/QM77 Express Chipsets
			FSP, the default ImageBase is oxFFF80000.
32	4	ImageAttribute	Attributes of the FSP binary. This field is not currently used.
36	4	CfgRegionOffset	Offset of the configuration region. This offset is relative to the FSP binary base address.
40	4	CfgRegionSize	Size of the configuration region.

Byte Offset	Size in Bytes	Field	Description
44	4	ApiEntryNum	Number of API Entries this FSP supports. The current design supports 3 APIs as given below.
48	4	TempRamInitEntryOffset	The offset for the API to setup a temporary stack till the memory is initialized.
52	4	FspInitEntryOffset	The offset for the API to initialize the CPU and the Chipset (SOC).
56	4	NotifyPhaseEntryOffset	The offset for the API to inform the FSP about the different stages in the boot process.
60	4	Reserved	Reserved

5.1.1 Finding the FSP Header

The FSP binary follows the UEFI Platform Initialization Firmware Volume Specification format. The Firmware Volume (FV) format is described in the *Platform Initialization* (*PI) specification - Volume 3: Shared Architectural Elements* specification and can be downloaded from http://www.uefi.org/specifications/

FV is a way to organize/structure binary components and enables a standardized way to parse the binary and handle the individual binary components that make up the FV.

The FSP_INFORMATION_HEADER is a firmware file and is placed as the **first** firmware file within the firmware volume. All firmware files will have a GUID that can be used to identify the files, including the FSP Header file. The FSP header firmware file GUID is defined as **912740BE-2284-4734-B971-84B027353F0C**.

The boot loader can find the offset of the FSP header within the FSP binary by the following steps described below:

- Use EFI_FIRMWARE_VOLUME_HEADER to parse the FSP FV header and skip the standard and extended FV header.
- The EFI_FFS_FILE_HEADER with the FSP_FFS_INFORMATION_FILE_GUID is located at the 8-byte aligned offset following the FV header.
- The EFI_RAW_SECTION header follows the FFS File Header.
- Immediately following the EFI_RAW_SECTION header is the raw data. The format of this data is defined in the FSP_INFORMATION_HEADER structure.
- Please refer to Appendix B for a sample code snippet which does the above steps in a stackless environment.

5.1.2 FSP Header Offset

To simplify the integration of the FSP binary with a boot loader, the offset of the FSP header will be provided with the FSP binary documentation. In this case, the boot loader may choose to skip the generic algorithm to find the FSP header as described above, but instead use the hardcoded value for the FSP header offset. This approach is easier to implement from the boot loader side.

For the 3rd Generation Intel[®] Core[™] Processors with Mobile Intel[®] HM76/QM77 Express Chipsets FSP, the FSP header is placed at an offset of **0x94**. So, for example, if the FSP binary is placed at **0xFFF80000** after the final build, the FSP header can be located at **0xFFF80094**. This implies that

- 1. The offset of the TempRamInitEntry can be found at **0xFFF800C4**
- 2. The offset of the FspInitEntry can be found at **0xFFF800C8**
- 3. The offset of the NotifyPhaseEntry can be found at **0xFFF800CC**

6 FSP Interface (FSP API)

6.1 Entry-Point Calling Assumptions

There are some requirements regarding the operating environment for FSP execution. It is the responsibility of the boot loader to set up this operating environment before calling the FSP API. These conditions have to be met before calling any entry point or the behavior is not determined. These conditions include:

- System is in flat 32-bit mode.
- Both the code and data selectors should have full 4GB access range.
- Interrupts should be turned off.
- The FSP API should be called only by the System BSP, unless otherwise noted.

Other requirements needed by individual FSP API will be covered in their respective sections.

6.2 Entry-Point Calling Convention

All FSP APIs defined in the FSP information header are 32-bit only. The FSP API interface is similar to the default C _cdecl convention. Like the default C _cdecl convention, with the FSP API interface:

- All parameters are pushed onto the stack in a right-to-left order before the API is called.
- The calling function needs to clean the stack up after the API returns.
- The return value is returned in the EAX register. All the other registers are preserved.

There are, however, a couple of notable exceptions with the FSP API interface convention. Please refer to individual API descriptions for any special notes and these exceptions.

6.3 Exit Convention

- The TempRamInit API will preserve all general purpose registers except EAX, ECX, and EDX. Because this FSP API is executing in a stackless environment, the floating point registers may be used by the FSP to save/return other general purpose registers to the boot loader.
- The FspInit and the FspNotify interfaces will preserve all the general purpose registers except "eax". The return status will be passed back through the eax register.
- The FSP reserves some memory for its internal use and the memory region that is used by the FSP will be passed back though a HOB. The boot loader is expected to not to use this memory except to parse the HOB output. The boot loader is also expected to mark this memory as reserved when constructing the memory map information to be passed to the OS.

6.4 TempRamInitEntry

This FSP API is called soon after coming out of reset and before memory and stack are available. This FSP API will load the microcode update, enable code caching for the region specified by the boot loader and also setup a temporary stack to be used till main memory is initialized.

A hardcoded stack can be setup with the following values and the "esp" register initialized to point to this hardcoded stack.

- 1. The return address where the FSP will return control after setting up a temporary stack
- 2. A pointer to the input parameter structure

However, since stack is in ROM and not writeable, this FSP API cannot be called using the "call" instruction, but needs to be jumped to. This API should be called only once after the system comes out of the reset, and it must be called before any other FSP APIs. The system needs to go through a reset cycle before this API can be called again. Otherwise, unexpected results may occur.

6.4.1 Prototype
 typedef
 FSP_STATUS
 (FSPAPI *FSP_TEMP_RAM_INIT) (
 IN FSP_TEMP_RAM_INIT_PARAMS *TempRamInitParamPtr
);

6.4.2 Parameters

TempRaminitParamPtr

Address pointer to the FSP_TEMP_RAM_INIT_PARAMS structure. The structure definition is provided below under Related Definitions. The structure has a pointer to the base of a code region and the size of it. The FSP enables code caching for this region. Enabling code caching for this region should not take more than one MTRR pair. The structure also has a pointer to a microcode region and its size. The microcode region may have multiple microcodes packed together one after the other and the FSP will try to load all the microcodes that it finds in the region that are compatible with the silicon it is supporting.

This microcode region will be remembered by FSP so that it can be used to load microcode for all APs later on during the FspInit API call.

6.4.3 Related Definitions

typedef struct {

UINT32	<i>MicrocodeRegionBase,</i>
UINT32	MicrocodeRegionLength,
UINT32	CodeRegionBase,
UINT32	CodeRegionLength

} FSP_TEMP_RAM_INIT_PARAMS;

6.4.3.1 Return Values

If this function is successful, the FSP initializes the ECX and EDX registers to point to a temporary but writeable memory range available to the boot loader and returns with FSP_SUCCESS in register EAX. Register ECX points to the start of this temporary memory range and EDX points to the end of the range. Boot loader is free to use the whole range described. Typically the boot loader can reload the ESP register to point to the end of this returned range so that it can be used as a standard stack.

Note: This returned range is just a sub-region of the whole temporary memory initialized by the processor. FSP maintains and consumes the remaining temporary memory. It is important for the boot loader not to access the temporary memory beyond the returned boundary.

FSP_SUCCESS	Temp RAM was initialized successfully. ESP register will be initialized as described below.
FSP_INVALID_PARAMETER	Input parameters are invalid.
FSP_NOT_FOUND	No valid microcode was found in the microcode region.
FSP_UNSUPPORTED	The FSP calling conditions were not met.

6.4.3.2 Sample Code

```
.global basic_init
basic_init:
  .
  •
  •
  #
  # Parse the FV to find the FSP INFO Header
  #
  lea
        findFspHeaderStack, %esp
        find_fsp_info_header
  jmp
findFspHeaderDone:
                                   # save fsp header address in
 mov
        %eax, %ebp
ebp
        0x30(%ebp), %eax
                                   # TempRamInit offset entry in
 mov
the header
  add
        0xlc(%ebp), %eax
                                   # add the FSP base to get the
API address
  lea
        tempRamInitStack, %esp
                                  # initialize to a rom stack
  #
  # call FSP PEI to setup temporary Stack
  #
  jmp
        *%eax
temp_RamInit_done:
  addl $4, %esp
         $0, %eax
  cmp
        continue
  iΖ
```

```
#
 # TempRamInit failed, dead loop
 #
 jmp
      .
continue:
 #
 # Save FSP_INFO_HEADER in ebx
 #
 mov
        %ebp, %ebx
 #
 # setup bootloader stack
 # ecx: stack base
 # edx: stack top
 #

  .long temp_RamInit_done
  .long tempRamInitParams
                           # pointer to parameters
```

Note: early_init(FSP_INFO_HEADER *fsp_info) is described in section 6.5.5.

6.4.4 Description

The entry to this function is in a stackless/memoryless environment. After the boot loader completes its initial steps, it finds the address of the FSP INFO HEADER and then from the header finds the offset of the TempRamInit function. It then converts the offset to an absolute address by adding the base of the FSP binary and calls the TempRamInit function.

This temporary memory is intended to be primarily used by the boot loader as a stack. After this stack is available, the boot loader can switch to using C functions. This temporary stack should be used to do only the minimal initialization that needs to be done before memory can be initialized by the next call into the FSP.

The FSP initializes the ECX and EDX registers to point to a temporary but writeable memory range. Register ECX points to the start of this temporary memory range and EDX points to the end of the range. The size of the temporary stack for the platform can be calculated by taking the range between EDX and ECX.

6.5 FspInitEntry

This FSP API is called after TempRamInitEntry. This FSP API initializes the memory, the CPU and the chipset to enable normal operation of these devices. This FSP API accepts a pointer to a data structure that will be platform dependent and defined for each FSP binary. This will be documented with each FSP release.

The boot loader provides a continuation function as a parameter when calling FspInit. After FspInit completes its execution, it will not return to the boot loader from where it was called, but instead will return control to the boot loader by calling the continuation function.

6.5.1 Prototype

```
typedef
FSP_STATUS
(FSPAPI *FSP_FSP_INIT) (
INOUT FSP_INIT_PARAMS *F;
)
```

*FspInitParamPtr);

6.5.2 Parameters

FspInitParamPtr

Address pointer to the FSP_INIT_PARAMS structure

6.5.3 Related Definitions

typedef struct {		
VOID	*NvsBuffer	Ptr;
VOID	*RtBufferF	Ptr;
CONTINU	ATION_PROC	ContinuationFunc;
<pre>} FSP_INIT_PARAMS;</pre>		

NvsBufferPtr	Pointer to the non-volatile storage data buffer.
RtBufferPtr	Pointer to the runtime data buffer.
ContinuationFunc	Pointer to a continuation function provided by the boot loader.

typedef VOID (* CONTINUATION_PROC)(
 IN FSP_STATUS Status,
 IN VOID *HobListPtr
);

Status	Status of the FSP Init API.
HobBufferPtr	Pointer to the HOB data structure defined in the PI specification.

The FSP_INIT_RT_BUFFER for the 3rd Generation Intel[®] Core[™] Processors with Mobile Intel[®] HM76/QM77 Express Chipsets FSP is defined as below.

```
typedef struct {
 UINT32
                    *StackTop;
 UINT32
                    BootMode;
} FSP_INIT_RT_COMMON_BUFFER;
typedef struct {
 const MEM CONFIG
                       *MemoryConfig;
} FSP_INIT_RT_PLATFORM_BUFFER;
typedef struct {
 UINT8
         HTEnable;
 UINT8
          TurboEnable;
 UINT8
        MemoryDownEnable;
 UINT8
         FastBootEnable;
} PLATFORM_CONFIG;
typedef struct {
 const
         PLATFORM_CONFIG
                            *PlatformConfig;
} FSP_INIT_RT_CONFIG_BUFFER;
typedef struct {
 FSP_INIT_RT_COMMON_BUFFER
                              Common;
 FSP_INIT_RT_CONFIG_BUFFER
                              PlatformConfiguration;
 FSP_INIT_RT_PLATFORM_BUFFER RtPlatform;
} FSP_INIT_RT_BUFFER;
```

MEM_CONFIG is the data structure for Memory Down. Refer Appendix C for its structure definitions.

6.5.4 Return Values

FSP_SUCCESS	FSP execution environment was initialized successfully.
FSP_INVALID_PARAMETER	Input parameters are invalid.
FSP_UNSUPPORTED	The FSP calling conditions were not meet.
FSP_DEVICE_ERROR	FSP initialization failed

6.5.5 Sample Code

{

.

.

typedef VOID (* CONTINUATION_PROC)(EFI_STATUS Status, VOID
*HobListPtr);

const PLATFORM_CONFIG CpuConfigData = {0x01, 0x00, 0x00, 0x00};

typedef struct {

void *NvsBufferPtr;

void *RtBufferPtr;

CONTINUATION_PROC ContinuationFunc;

} FSP_INIT_PARAMS;

#define FSPAPI __attribute__((cdecl))

```
typedef FSP_STATUS (FSPAPI *FSP_FSP_INIT) (FSP_INIT_PARAMS
*FspInitParamPtr);
```

#define BOOTLOADER_STACKTOP 0x98000 // Porting required

void early_init (FSP_INFORMATION_HEADER *fsp_info)

uint32_t	FspInitEntry;
FSP_FSP_INIT	FspInitApi;
volatile FSP_INIT_PARAMS	FspInitParams;
volatile FSP_INIT_RT_BUFFER	FspRtBuffer;

}

{

```
memset((void*)&FspRtBuffer, 0, sizeof(FSP_INIT_RT_BUFFER));
  FspRtBuffer.Common.StackTop = BOOTLOADER_STACKTOP;
  FspRtBuffer.RtPlatform.MemoryConfig =NULL;
  FspRtBuffer.PlatformConfiguration.PlatformConfig =
    &CpuConfigData;
  FspInitParams.NvsBufferPtr = 0;
  FspInitParams.RtBufferPtr = (FSP_INIT_RT_BUFFER *)&FspRtBuffer;
  FspInitParams.ContinuationFunc =
    (CONTINUATION_PROC)ContinuationFunc;
  FspInitApi = (FSP_FSP_INIT)(fsp_info->ImageBase + fsp_info
    ->FspInitEntry);
  FspInitApi(&FspInitParams);
  /* Should never return. Control will continue from
   ContinuationFunc */
 while (1);
void ContinuationFunc (EFI STATUS Status, VOID *HobListPtr)
 /* Check status for -1, indicating that we need to do a reset */
    if (Status == 0xFFFFFFFF)
    {
        /* Trigger the reset */
        outb(0x0cf9, 0x06);
        /* Should never return */
        while (1);
    }
```

```
/* Update global variables */
FspHobListPtr = HobListPtr;
/* Get the pointer to the FSP header the same way as in
basic_init */
asm ("call find_fsp_info_header; movl %%eax, %0" : "=r"
(fsp_info_header) :);
    /* Continue the boot */
    advancedInit ();
    /* Should never return */
    while (1);
}
```

6.5.6 Enabling Fast Boot

The shaded lines in the sample code below highlight the things that need to be changed to enable fast boot in the bootloader. First, the FastBootEnable field needs to be set to TRUE in the PLATFORM_CONFIG structure:

```
// Platform Configuration
const PLATFORM_CONFIG PlatformConfig = {
   TRUE, // Hyperthreading
   FALSE, // Turbo Mode
   FALSE, // Memory Down
   TRUE, // Fast Boot
};
```

The boot loader should implement code to save and read back the HOB data to/from non-volatile storage. The sample code below shows an example implementation for passing the HOB data back to the FSP thru the NvsBufferPtr pointer. For the first boot, the data buffer that this pointer points to should contain either all zeroes or all 0xFFs so that the FSP can recognize it as being uninitialized. For subsequent boots, the data buffer that this pointer points to should contain valid memory training data that was generated by the FSP during the first boot and was saved by boot loader to the data buffer in non-volatile storage.

```
void early_init (FSP_INFO_HEADER *fsp_info)
ł
 FSP_FSP_INIT
                       FspInitEntry;
```

```
FSP_INIT_PARAMS
                     FspInitParams;
FSP_INIT_RT_BUFFER
                     FspRtBuffer;
                    *NvsBufferPtr;
VOID
```

... // Some init code.

```
// Get pointer to saved NVSTORAGE HOB data
  NvsBufferPtr = ... // Platform-specific
  memset((void*)&FspRtBuffer, 0, sizeof(FSP_INIT_RT_BUFFER));
  FspRtBuffer.Common.StackTop = &_stack_top;
  FspRtBuffer.PlatformConfiguration.PlatformConfig =
&PlatformConfig;
  FspRtBuffer.Platform.MemoryConfig = NULL;
  FspInitParams.NvsBufferPtr = NvsBufferPtr;
  FspInitParams.RtBufferPtr = (FSP_INIT_RT_BUFFER *)&FspRtBuffer;
  FspInitParams.ContinuationFunc =
(CONTINUATION PROC)ContinuationFunc;
  FspInitEntry = (FSP_FSP_INIT)(fsp_info->ImageBase + fsp_info-
>FspInitEntry);
  FspInitEntry(&FspInitParams);
  /* Should never return. Control will continue from
ContinuationFunc */
  while (1);
}
After FspInitEntry is done, control is returned to the boot
loader via the ContinuationFunc function, which is passed a
pointer to the HOB list. The boot loader should save this pointer
for use later.
volatile void *FspHobListPtr;
void ContinuationFunc (EFI STATUS Status, VOID *HobListPtr)
{
    . . .
    /* Update global variables */
```

```
FspHobListPtr = HobListPtr;
```

```
/* Continue the boot */
advancedInit ();
/* Should never return */
while (1);
```

. . .

}

One of the HOBs in the HOB list contains the Non-Volatile Storage data, which includes the memory training data required for fast boot. It's the data from this HOB that must be saved into non-volatile storage to be used in subsequent boots. This data is extracted from the HOB list with the following function, which depends upon values and functions that are defined in fsphob.h and are implemented fsphob.c, both of which are included with the files that are packaged with the FSP.

```
#include "fsphob.h"
```

```
void GetFspHobDataForNVStorage(
 VOID
               **ppHobData,
               *pHobDataSize
  uint16_t
  )
{
 EFI GUID
                          Guid =
FSP NON VOLATILE STORAGE HOB GUID;
 uint8 t
                           *Hob;
 EFI_HOB_GENERIC_HEADER *HobHdr;
 Hob = GetFirstGuidHob(&Guid);
  if (!Hob) {
    *ppHobData = NULL;
    *pHobDataSize = 0;
  } else {
    *ppHobData = (VOID *)GET_GUID_HOB_DATA(Hob);
    HobHdr = (EFI_HOB_GENERIC_HEADER *)Hob;
    *pHobDataSize = GET_GUID_HOB_DATA_SIZE(HobHdr);
  }
}
```

This function is called from the boot loader after everything else is successfully initialized, right before calling FspNotifyPhase(EnumInitPhaseReadyToBoot), and the HOB data is saved to non-volatile storage. Sample code below shows that this function is called inside advancedInit.

```
void advancedInit()
{
    VOID *HobData;
    uint16_t HobDataSize;
    ...
    /* NVS data to save */
    GetFspHobDataForNVStorage(&HobData, &HobDataSize);
    /* Check result */
    if ((HobData != NULL) && (HobDataSize > 0))
    {
        /* Check if data will fit in available NV storage */
        if (HobDataSize <= NVRAM_SIZE) // Platform-specific
        {
        /*
    }
}
```

```
/* Save NVSTORAGE HOB data
... // Platform-specific
}
}
/* Notify FSP for ReadyToBoot */
FspNotifyPhase(EnumInitPhaseReadyToBoot);
...
}
```

6.5.7 Description

One of the data that will be part of the FSP_INIT_PARAMS. RtBufferPtr will be the "StackTop". This will pass the address of the StackTop where the boot loader wants to establish the stack once memory is initialized and available for use. ContinuationFunc is a function entry point that will be jumped to at the end of the FspInit() execution to transfer control back to the boot loader. Please note the FspInit API will initialize the permanent memory and switch the stack from temporary to permanent memory as specified by StackTop. Sometimes switching stack in a function can cause some unexpected execution results because the compiler is not aware of the stack change during runtime and the precompiled code may still refer to the old stack for data and pointers. A stack switch will then require assembly code to patch up the data for the new stack location, which may lead to compatibility issues. To avoid such possible compatibility issues introduced by different compilers and ease the integration of FSP with a boot loader, the API will use the "ContinuationFunction" parameter to continue the boot loader execution flow rather than return as a normal C function. Although this API will be called as a normal C function, it will never return to one.

The FSP will need to get some parameters from the boot loader when it's initializing the silicon. These parameters are passed from the boot loader to the FSP through the RtBuffer structure pointer.

The FSP may need to initialize memory under special circumstances, such as during an S3 resume and fast boot mode. This set of parameters will be returned by the FSP to the boot loader during a normal boot. The boot loader is expected to store these parameters in a non-volatile memory, comparable to SPI flash, and return a pointer to this structure (through NvsBufferPtr) when it is requesting the FSP to initialize the silicon under these special circumstances.

During execution the FSP will build a series of data structures containing information useful to the boot loader, such as information on system memory.

This API should be called only once after the TempRamInit API.

7 FSP Output

The FSP builds a series of data structures called the Hand-Off-Blocks (HOBs) as it progresses through initializing the silicon. These data structures conform to the HOB format as described in the *Platform Initialization (PI) specification - Volume 3: Shared Architectural Elements* specification and can be downloaded from http://www.uefi.org/specifications/

The user of the FSP binary is strongly encouraged to go through the specification mentioned above to understand the HOB design details and create a simple infrastructure to parse the HOBs, because the same infrastructure can be reused with different FSP across different platforms

It's left to the boot loader developer to decide on how to consume the information passed through the HOBs produced by the FSP. For example, even the specification mentioned above describes about 9 different HOBs; most of this information may not be relevant to a particular boot loader. For example, a boot loader design may be interested only in knowing the amount of memory populated and may not care about any other information.

The section below describes the GUID HOBs that are produced by the FSP. GUID HOB structures are non-architectural in the sense that the structure of the HOB needs is not defined in the HOB specifications. So the GUID and the data structure are documented below to enable the boot loader to consume these HOB data.

Please refer to the specification for details about the HOBs described in the *Platform Initialization (PI) specification - Volume 3: Shared Architectural Elements* specification.

7.1 Boot Loader Temporary Memory Data HOB

As described in the FspInit API, the system memory is initialized and the whole temporary memory is destroyed during this API call. However, the sub region of the temporary memory returned in the TempRamInit API may still contain boot loader-specific data, which might be useful for boot loader even after the FspInit call. So before destroying the temporary memory, all contents in this sub region is migrated to the permanent memory. FSP builds a boot loader temporary memory data HOB, which the boot loader can to access the data saved in the temporary memory after FspInit API if necessary. If the boot loader does not care about the previous data, this HOB can be simply ignored.

This HOB follows the EFI_HOB_GUID_TYPE format with the name GUID defined as below:

#define FSP_BOOTLOADER_TEMPORARY_MEMORY_HOB_GUID \

```
{ 0xbbcff46c, 0xc8d3, 0x4113, { 0x89, 0x85, 0xb9, 0xd4, 0xf3,
0xb3, 0xf6, 0x4e } ;
```

7.2 Non-Volatile Storage HOB

The NVS buffer that is used by FSP to initialize the silicon during S3 resume, fast boot mode, etc., is passed through a GUID HOB with a GUID HOB defined as below. The boot loader is expected to save the data in a non-volatile storage memory area and initialize the FspInit parameter properly when requesting special initialization sequences such as S3 resume, fast boot mode, etc.

This HOB follows the EFI_HOB_GUID_TYPE format with the name GUID defined as below:

#define FSP_NON_VOLATILE_STORAGE_HOB_GUID \

{ 0x721acf02, 0x4d77, 0x4c2a, { 0xb3, 0xdc, 0x27, 0xb, 0x7b, 0xa9, 0xe4, 0xb0 } ;;

7.3 HOB Sample Code

An example function using the HOB infrastructure and getting the memory information is provided below.

7.3.1 Hob Infrastructure Sample Code

Please refer to the Appendix - A for sample code.

7.3.2 Hob Parsing Sample Code

```
void
GetMemorySize (
 UINT32
                   *LowMemoryLength,
  void
                   *HobBufferPtr
  )
{
 EFI PEI HOB POINTERS
                          Hob;
  *LowMemoryLength = 0x100000;
  11
  // Get the HOB list for processing
  11
  Hob.Raw = HobBufferPtr;
  11
  // Collect memory ranges
  11
 while (!END OF HOB LIST (Hob)) {
    if (Hob.Header->HobType == EFI_HOB_TYPE_RESOURCE_DESCRIPTOR)
{
      if (Hob.ResourceDescriptor->ResourceType ==
EFI_RESOURCE_SYSTEM_MEMORY) {
```

FSP Output

```
11
        \ensuremath{{/}} Need memory above 1MB to be collected here
        11
        if (Hob.ResourceDescriptor->PhysicalStart >= 0x100000 &&
           Hob.ResourceDescriptor->PhysicalStart <
(EFI_PHYSICAL_ADDRESS) 0x10000000) {
          *LowMemoryLength += (UINT32) (Hob.ResourceDescriptor-
>ResourceLength);
        }
      }
    }
   Hob.Raw = GET_NEXT_HOB (Hob);
  }
 return;
}
void boot_loader_rom_stage_fn ()
{
    .
    .
    .
 /* call FSP PEI to setup MRC and other CS init */
    .
    .
    .
 /* Get the memory size by parsing the HOB returned from the FSP
* /
 GetMemorySize (&LowMemoryLength, FspInitParams.HobBufferPtr);
    •
    .
    .
}
```

7.3.3 GUID HOB Sample Code

```
void *
GetGuidHobData (
    CONST EFI_GUID *Guid
    )
{
    VOID *GuidHob;
    GuidHob = GetFirstGuidHob (Guid);
    if (GuidHob == NULL) {
        return NULL;
    }
    return (void *)GET_GUID_HOB_DATA (GuidHob);
}
```

8 FSP Configuration Firmware File

The FSP binary contains a configurable data region which will be used by the FSP during the initialization. Typically this is the default parameters used by the PEIMs in the FSP. The parameters can be statically customized using a separate tool as explained in the tools section. The tool will use a Binary Setting File (BSF) to understand the layout of the configuration region within the FSP.

9 Tools

A Binary Configuration Tool (BCT) will be provided with the FSP binary that can used on the FSP binary to allow a user to modify certain well defined configuration values in the FSP binary. The BCT will typically provide a graphical user interface (GUI). The Binary Configuration Tool (BCT) will be provided with separate documentation that explains the usage of the tool.

Other Host Boot Loader Concerns

10 Other Host Boot Loader Concerns

10.1 Power Management

Intel[®] FSP does not provide power management functions besides making power management features available to the host boot loader. ACPI is an independent component of the boot loader, and it will not be included in Intel[®] FSP.

10.2 Bus Enumeration

Intel[®] FSP will initialize the CPU and the companion chips to a state that all bus topology can be discovered by the host boot loader.

10.3 Security

Intel[®] FSP does not provide security features besides making security features available to the host boot loader.

10.4 64-bit Long Mode

Intel[®] FSP operates in 32-bit mode; it is the responsibility of the host boot loader to transition to 64-bit Long Mode if desired.

10.5 Pre-OS Graphics

Intel[®] FSP does not include graphics initialization function. For pre-OS graphics initialization solutions, please contact your Intel representative.

Appendix A – HOB Parsing Sample Code

The sample code provided here was derived from the EDK2 source available for download at

Appendix B – Sample Code to Find FSP Header

The sample code provided below parses the FSP binary and finds the address of the FSP Header within it.

As the FV parsing has to be done before stack is available, a mix of assembly language code and C code is used. The C code is used to parse the data structures and find the FSP INFO Header. However, since the compiler will add prolog or epilog code to the C function, inline assembly is used to bypass those portions of the C code.

The sample code provided here uses header files derived from the EDK2 source available for download at

```
http://sourceforge.net/apps/mediawiki/tianocore/index.php?title=EDK2
```

```
#include "PiFirmwareVolume.h"
#include "PiFirmwareFile.h"
void __attribute__((optimize("00"))) find_fsp_header ()
{
    volatile register UINT8 *ptr asm ("eax");
    __asm___volatile__ (
        ".global find_fsp_info_header \n\t"
        "find_fsp_info_header:\n\t"
      );
    11
    // Start at the FSP / FV Header base
    11
   ptr = (UINT8 *)0xFFF80000;
    11
    // Validate FV signature _FVH
    11
    if (((EFI_FIRMWARE_VOLUME_HEADER *)ptr)-> Signature !=
0x4856465F) {
     ptr = 0;
      goto NotFound;
    }
    11
    // Add the Ext Header size to the Ext Header base to go to
    // the end of FV header
    11
   ptr += ((EFI FIRMWARE VOLUME HEADER *)ptr)->ExtHeaderOffset;
   ptr += ((EFI FIRMWARE VOLUME EXT HEADER *)ptr)-
>ExtHeaderSize;
```

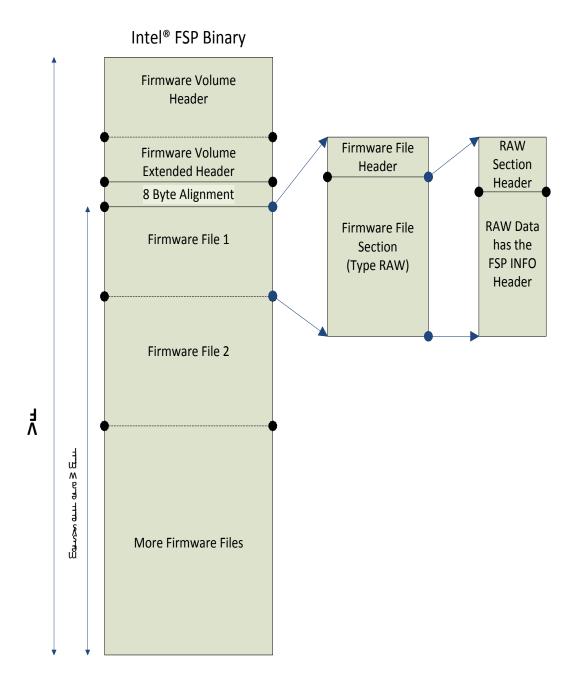

```
11
    // Align the pointer to 8 bytes and it will point to FFS
    // header
    11
   ptr = (UINT8 *)(((UINTN)ptr + 7) & 0xFFFFFF8);
    11
    // Now ptr is pointing to thr FFS Header. Verify if the GUID
    // matches the FSP INFORMATION HEADER GUID
    11
    if ((((UINT32 *)&(((EFI_FFS_FILE_HEADER *)ptr)->Name))[0] !=
0x912740BE) || (((UINT32 *)&(((EFI_FFS_FILE_HEADER *)ptr)-
>Name))[1] != 0x47342284)
                            || (((UINT32
*)&(((EFI_FFS_FILE_HEADER *)ptr)->Name))[2] != 0xB08471B9)
                                                               (((UINT32 *)&(((EFI_FFS_FILE_HEADER *)ptr)->Name))[3] !=
0x0C3F3527)) {
       ptr = 0;
        goto NotFound;
    }
    11
    // Add the FFS Header size to the base to find the Raw
    // section Header
    11
    ptr += sizeof(EFI_FFS_FILE_HEADER);
    if (((EFI RAW SECTION *)ptr)->Type != EFI SECTION RAW) {
       ptr = 0;
        goto NotFound;
    }
    11
    // Add the Raw Header size to the base to find the FSP INFO
    // Header
    11
   ptr += sizeof(EFI_RAW_SECTION);
NotFound:
    __asm___volatile__ ("ret");
}
```

Now, call this function using a temporary ROM stack containing the return address and bypass the prolog or epilog code of the C function like below.

```
lea findFspHeaderStack, %esp
jmp find_fsp_entry
findFspHeaderStack:
  .align 4
  .long findFspHeaderDone
findFspHeaderDone:
```

A pictorial representation of the data structures that we parse in the above code is given below.

Appendix C – Data Structure for Memory Down

```

C.1 Sample Code

Memory Down support is required when the hardware design does not use standard DIMMs or SO-DIMMs, but instead has the memory soldered down to the board, and the serial presence detect (SPD) data is not stored in a standard SPD EEPROM such as is found on a standard DIMM or SO-DIMM. In this situation, the boot loader must provide a means to pass the SPD data to the FSP.

The shaded lines in the sample code below highlight the things that need to be changed to support memory down.

To enable memory down, the MemoryDownEnable field needs to be set to TRUE in the PLATFORM_CONFIG structure:

```
// Platform Configuration
const PLATFORM_CONFIG PlatformConfig = {
   TRUE, // Hyperthreading
   FALSE, // Turbo Mode
   TRUE, // Memory Down
   FALSE, // Fast Boot
};
```

The boot loader must provide a board-specific means of reading the SPD data from where it is stored on the hardware using a function with a prototype similar to this:

The following sample code shows how to provide the SPD data to the FSP for a hardware design that implements memory on Channel A Bank 0 and Channel B Bank 0.

```
void early_init (FSP_INFO_HEADER *fsp_info)
{
   FSP_FSP_INIT FspInitEntry;
   FSP_INIT_PARAMS FspInitParams;
   FSP_INIT_RT_BUFFER FspRtBuffer;
   MEM_CONFIG MemoryConfig;
```

```
... // Some init code.
```

```
// Initialize the memory config
memset(&MemoryConfig, 0, sizeof(MemoryConfig));
// Channel A Bank 0 and Channel B Bank 0 exist
MemoryConfig.ChannelABank0.Exists = 1;
MemoryConfig.ChannelBBank0.Exists = 1;
```

```
// Read the SPD data from the hardware
ReadSpdData(0, 0, &MemoryConfig.ChannelABank0.SpdData); //
Platform-specific
ReadSpdData(1, 0, &MemoryConfig.ChannelBBank0.SpdData); //
Platform-specific
memset((void*)&FspRtBuffer, 0, sizeof(FSP_INIT_RT_BUFFER));
```

```
FspRtBuffer.Common.StackTop = &_stack_top;
FspRtBuffer.PlatformConfiguration.PlatformConfig =
&PlatformConfig;
FspRtBuffer.Platform.MemoryConfig = &MemoryConfig;
FspInitParams.RtBufferPtr = (FSP_INIT_RT_BUFFER
*)&FspRtBuffer;
FspInitParams.ContinuationFunc =
(CONTINUATION_PROC)ContinuationFunc;
FspInitEntry = (FSP_FSP_INIT)(fsp_info->ImageBase + fsp_info-
>FspInitEntry);
FspInitEntry(&FspInitParams);
/* Should never return. Control will continue from
ContinuationFunc */
while (1);
}
```

§
