§

1 Introduction

1.1 Purpose

The purpose of this document is to describe the steps required to integrate the Intel® FSP for Intel® Atom™ Processor E6xx Series with Intel® Platform Controller Hub EG20T into a boot loader solution.

1.2 Intelligent Systems and Embedded Ecosystem Overview

Contrasting the PC ecosystem where hardware and software architecture are following a set of industry standards, the Intelligent Systems (embedded) ecosystem often does not adhere to the same industry standards. Design engineers for Intelligent Systems and Embedded Systems frequently combine components from different vendors with a set of very distinct functions in mind.

The criteria for picking the right boot loader are often based on boot speed and code size. The boot loader also frequently has close ties with the OS from a functionality perspective. To give freedom to customers to choose the best boot loader for their applications, Intel provides the Firmware Support Package (FSP) to satisfy the needs of design engineers.

1.3 Intended Audience

This document is targeted at all platform and system developers who need to consume FSP binaries in their boot loader solutions. This includes, but is not limited to: system BIOS developer, boot loader developer, system integrators, as well as end users.

1.4 Related Documents

- Platform Initialization (PI) Specification located at http://www.uefi.org/specs/.
- *Intel® Firmware Support Package: Introduction* Guide – available at www.intel.com/fsp
- Binary Configuration Tool for Intel® Firmware Support Package – available at http://www.intel.com/fsp

1.5 Conventions

To illustrate some of the points better, the document will use code snippets. The code snippets follow **the GNU C Compiler** and **GNU Assembler** syntax.

1.6 Acronyms and Terminology

BSP	Boot Strap Processor
BWG	BIOS Writer's Guide
CRB	Customer Reference Board
FSP	Firmware Support Package
FSP API	Firmware Support Package Interface
FWG	Firmware Writer's Guide
IVI	In Vehicle Infotainment
NBSP	Node BSP
RSM	Resume to OS from SMM
SBSP	System BSP
SMI	System Management Interrupt
SMM	System Management Mode
TSEG	Memory Reserved at the Top of Memory to be used as SMRAM
TXE	Trusted Execution Engine/Environment

2 FSP Overview

2.1 Design Philosophy

Intel recognizes that it holds the key programming information that is crucial for initializing Intel silicon. After Intel provides the key information, most experienced firmware engineers can make the rest of the system work by studying specifications, porting guides, and reference code.

2.2 Technical Overview

The Intel® Firmware Support Package (FSP) provides chipset and processor initialization in a format that can easily be incorporated into many existing boot loaders.

The FSP will perform all the necessary initialization steps as documented in the BWG including initialization of the CPU, memory controller, chipset and certain bus interfaces, if necessary.

FSP is not a stand-alone boot loader; therefore it needs to be integrated into a host boot loader to carry out other boot loader functions, such as: initializing non-Intel components, conducting bus enumeration, and discovering devices in the system and all industry standard initialization.

3 FSP Integration

The FSP binary can be integrated easily into many different boot loaders, such as Coreboot, etc. and also into embedded OS directly.

Below are some required steps for the integration:

- Customizing

  The static FSP configuration parameters are part of the FSP binary and can be customized by external tools that will be provided by Intel.

- Rebasing

  The FSP is not Position Independent Code (PIC) and the whole FSP has to be rebased if it is placed at a location which is different from the preferred address specified during building the FSP.

- Placing

  Once the FSP binary is ready for integration, the boot loader build process needs to be modified to place this FSP binary at the specific rebasing location identified above.

- Interfacing

  The boot loader needs to add code to setup the operating environment for the FSP, call the FSP with the correct parameters and parse the FSP output to retrieve the necessary information returned by the FSP.

3.1 Assumptions Used in this Document

The Intel® FSP for Minnow is built with a preferred base address of 0xFFFC0000 and so the reference code provided in the document assumes that the FSP is placed at 0xFFFC0000 after the final boot loader build.

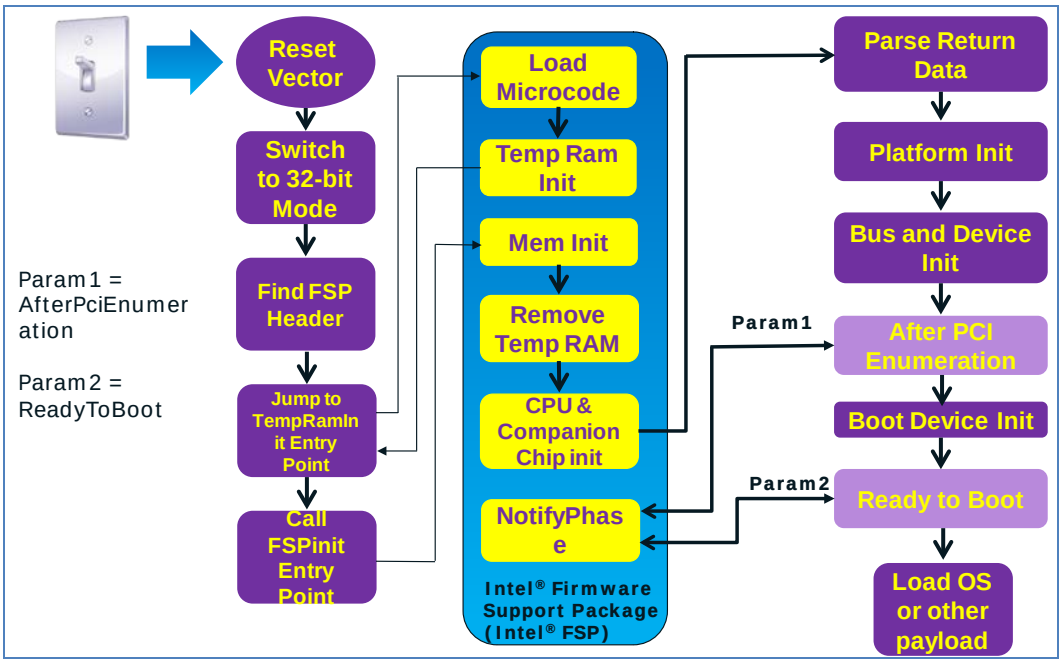
3.2 FSP Image Revision

To FSP information header contains an Image Revision field that provides the revision of the FSP binary. This is an important field to consider while integrating the FSP as API parameters could change over FSP revisions. The FSP API parameters documented in this integration guide are applicable for the Image Revisions specified in this document.

The current version of the FSP is GOLD 01 and the ImageRevision in the FSP Header is 0x00000301.

4 Boot Flow

The figure below shows the boot flow from the reset vector to the OS handoff for a typical boot loader. The APIs are described in more detail in the following sections.



5 FSP Binary Format

The FSP is distributed in binary format. The FSP binary contains an FSP specific **FSP_INFORMATION_HEADER** structure, the initialization code/data needed by the Intel Silicon supported by the FSP and a configuration region that allows the boot loader developer to customize some of the settings through a tool provided by Intel.

5.1 FSP Header

The FSP header conveys the information required by the boot loader to interface with the FSP binary such as providing the addresses for the entry points, configuration region address, etc.

Byte Offset	Size in Bytes	Field	Description
0	4	Signature	'FSPH'. Signature for the FSP Information Header.
4	4	HeaderLength	Length of the header
8	3	Reserved	Reserved
11	1	HeaderRevision	Revision of the header.
12	4	ImageRevision	Revision of the FSP Binary. The ImageRevision can be decoded as follows 0..7 - Minor Version 8..15 - Major Version 16..31 - Reserved
16	8	Image Id	8-byte signature string that will help match the FSP Binary to a supported hardware configuration. For Intel® FSP for Minnow, the ImageId is "MNW-FSP0"
24	4	ImageSize	Size of the entire FSP Binary.
28	4	ImageBase	FSP binary preferred base address. If the FSP binary will be located at the address different from the preferred address, the rebasing tool is required to relocate the base before the FSP binary integration.
32	4	ImageAttribute	Attributes of the FSP binary. This field is not currently used.

Byte Offset	Size in Bytes	Field	Description
36	4	CfgRegionOffset	Offset of the configuration region. This offset is relative to the FSP binary base address.
40	4	CfgRegionSize	Size of the configuration region.
44	4	ApiEntryNum	Number of API Entries this FSP supports. The current design supports 3 APIs as given below.
48	4	TempRamInitEntryOffset	The offset for the API to setup a temporary stack till the memory is initialized.
52	4	FspInitEntryOffset	The offset for the API to initialize the CPU and the Chipset (SOC).
56	4	NotifyPhaseEntryOffset	The offset for the API to inform the FSP about the different stages in the boot process.
60	4	Reserved	Reserved

5.1.1 Finding the FSP Header

The FSP binary follows the UEFI Platform Initialization Firmware Volume Specification format. The Firmware Volume (FV) format is described in the *Platform Initialization (PI) specification - Volume 3: Shared Architectural Elements* specification and can be downloaded from http://www.uefi.org/specs/

FV is a way to organize/structure binary components and enables a standardized way to parse the binary and handle the individual binary components that make up the FV.

The FSP_INFORMATION_HEADER is a firmware file and is placed as the **first** firmware file within the firmware volume. All firmware files will have a GUID that can be used to identify the files, including the FSP Header file. The FSP header firmware file GUID is defined as **912740BE-2284-4734-B971-84B027353F0C**.

The boot loader can find the offset of the FSP header within the FSP binary by the following steps described below:

- Use **EFI_FIRMWARE_VOLUME_HEADER** to parse the FSP FV header and skip the standard and extended FV header.
- The **EFI_FFS_FILE_HEADER** with the **FSP_FFS_INFORMATION_FILE_GUID** is located at the 8-byte aligned offset following the FV header.
- The **EFI_RAW_SECTION** header follows the FFS File Header.
- Immediately following the **EFI_RAW_SECTION** header is the raw data. The format of this data is defined in the **FSP_INFORMATION_HEADER** structure.
- Please refer Appendix – B for a sample code snippet which does the above steps in a stackless environment.

5.1.2 FSP Header Offset

To simplify the integration of the FSP binary with a boot loader, the offset of the FSP header will be provided with the FSP binary documentation. In this case, the boot loader may choose to skip the generic algorithm to find the FSP header as described above, but instead use the hardcoded value for the FSP header offset. This approach is easier to implement from the boot loader side.

For the Intel® FSP for Intel® Atom™ E6xx Series, the FSP header is placed at an offset of **0x94.**

6 FSP Interface (FSP API)

6.1 Entry-Point Calling Assumptions

There are some requirements regarding the operating environment for FSP execution. It is the responsibility of the boot loader to set up this operating environment before calling the FSP API. These conditions have to be met before calling any entry point or the behavior is not determined. These conditions include:

- System is in flat 32-bit mode.
- Both the code and data selectors should have full 4GB access range.
- Interrupts should be turned off.
- The FSP API should be called only by the System BSP, unless otherwise noted.

Other requirements needed by individual FSP API will be covered in their respective sections.

6.2 Data Structure Convention

All data structure definitions should be packed using compiler provided directives such as `#pragma pack(1)` to avoid alignment mismatch between FSP and the boot loader.

6.3 Entry-Point Calling Convention

All FSP APIs defined in the FSP information header are 32-bit only. The FSP API interface is similar to the default C __cdecl convention. Like the default C __cdecl convention, with the FSP API interface:

- All parameters are pushed onto the stack in right-to-left order before the API is called.
- The calling function needs to clean the stack up after the API returns.
- The return value is returned in the EAX register. All the other registers are preserved.

There are, however, a couple of notable exceptions with the FSP API interface convention. Please refer to individual API descriptions for any special notes and these exceptions.

6.4 Exit Convention

The TempRamInit API preserves all general purpose registers except EAX, ECX, and EDX. Because this FSP API is executing in a stackless environment, the floating point registers may be used by the FSP to save/return other general purpose registers to the boot loader.

The FspInit and the FspNotify interfaces will preserve all the general purpose registers except “eax”. The return status will be passed back through the eax register.

The FSP reserves some memory for its internal use and the memory region that is used by the FSP is passed back though a HOB. This is a Generic Resource HOB, but the owner field of the HOB will identify the owner as FSP. Please refer to the FSP Output section 7 for more details. The boot loader is expected to not to use this memory except to parse the HOB output. The boot loader is also expected to mark this memory as reserved when constructing the memory map information to be passed to the OS.

6.5 TempRamInitEntry

This FSP API is called soon after coming out of reset and before memory and stack are available. This FSP API will load the microcode update, enable code caching for the region specified by the boot loader and also setup a temporary stack to be used till main memory is initialized.

A hardcoded stack can be setup with the following values and the “esp” register initialized to point to this hardcoded stack.

1. The return address where the FSP will return control after setting up a temporary stack
2. A pointer to the input parameter structure

However, since stack is in ROM and not writeable, this FSP API cannot be called using the “call” instruction, but needs to be jumped to.

This API should be called only once after the system comes out the reset, and it must be called before any other FSP APIs. The system needs to go through a reset cycle before this API can be called again. Otherwise, unexpected results may occur. As described in FSP header, the TempRamInitEntry function Byte Offset in FSP binary is at 48.

6.5.1 Prototype

```
typedef
FSP_STATUS
(FSPAPI *FSP_TEMP_RAM_INIT) (
  IN  FSP_TEMP_RAM_INIT_PARAMS        *TempRamInitParamPtr
);
```

6.5.2 Parameters

TempRaminitParamPtr

Address pointer to the **FSP_TEMP_RAM_INIT_PARAMS** structure. The structure definition is provided below under Related Definitions. The structure has a pointer to the base of a code region and the size of it. The FSP enables code caching for this region. Enabling code caching for this region should not take more than one MTRR pair. The structure also has a pointer to a microcode region and its size. The microcode region may have multiple microcodes packed together one after the other and the FSP will try to load all the microcodes that it finds in the region that is compatible with the silicon it is supporting. This microcode region is remembered by FSP so that it can be used to load microcode for all APs later on during the FspInit API call.

6.5.3 Related Definitions

```
typedef struct {
  UINT32              MicrocodeRegionBase,
  UINT32              MicrocodeRegionLength,
  UINT32              CodeRegionBase,
  UINT32              CodeRegionLength
} FSP_TEMP_RAM_INIT_PARAMS;
```

6.5.3.1 Return Values

If this function is successful, the FSP initializes the **ECX and EDX** registers to point to a temporary but writeable memory range available to the boot loader and returns with FSP_SUCCESS in register EAX. Register ECX points to the start of this temporary memory range and EDX points to the end of the range. Boot loader is free to use the whole range described. Typically the boot loader can reload the ESP register to point to the end of this returned range so that it can be used as a standard stack.

Note: This returned range is just a sub-region of the whole temporary memory initialized by the processor. FSP maintains and consumes the remaining temporary memory. It is important for the boot loader not to access the temporary memory beyond the returned boundary.

FSP_SUCCESS	Temp RAM was initialized successfully.
FSP_INVALID_PARAMETER	Input parameters are invalid.
FSP_NOT_FOUND	No valid microcode was found in the microcode region.
FSP_UNSUPPORTED	The FSP calling conditions were not meet.
FSP_DEVICE_ERROR	Temp RAM initialization failed

6.5.3.2 Sample Code

```
cache_as_ram:
    post_code(0x20)

        /* call FSP PEI to setup temporary Stack */
    lea   findFspHeaderStack, %esp
    jmp   find_fsp_entry
findFspHeaderDone:
    /* EAX - *fsp_info_header of FSP_INFO_HEADER */

    /* call FSP PEI to setup temporary Stack */
    mov   %eax,   %ebp
    mov   0x30(%ebp), %eax
    add   0x1c(%ebp), %eax

    lea   tempRamInitStack, %esp     # initialize to a rom stack
    jmp   *%eax
temp_RamInit_done:
    addl  $4, %esp
    /* Do NOT change EBP until early_init */
    /* EBP - *fsp_info_header of FSP_INFO_HEADER */

    cmp   $0, %eax
    jz    continue

    /* TempRamInit failed, dead loop */
        jmp   .

    /* EAX - Return value, defined in
src/mainboard/intel/minnow/fsptypes.h */
continue:
```

```
    /* setup bootloader stack */
    /* ecx:  stack base */
    /* edx:  stack top */
    lea   -4(%edx), %esp

    /* Restore the BIST result. */
    xorl    %eax, %eax
    pushl   %eax

before_romstage:
    post_code(0x29)
    /* Call romstage.c main function. */
    /* Do NOT change EBP until early_init */
    call    main

    /* Save FSP_INFO_HEADER in ebx */
    mov    %ebp, %ebx

    /* call early init, set up MRC, CS init */
    push  %ebx    /* INPUT: EBX - *fsp_info_header of
FSP_INFO_HEADER */
    call  early_init    /* OUTPUT: EAX - *HobBufferPtr of
FSP_INIT_PARAMS */

  .
}
```

6.5.4 Description

The entry to this function is in a stackless/memoryless environment. After the boot loader completes its initial steps, it finds the address of the FSP INFO HEADER and then from the header finds the offset of the TempRamInit function. It then converts the offset to an absolute address by adding the base of the FSP binary and jumps to the TempRamInit function.

This temporary memory is intended to be primarily used by the boot loader as a stack. After this stack is available, the boot loader can switch to using C functions. This temporary stack should be used to do only the minimal initialization that needs to be done before memory can be initialized by the next call into the FSP.

The FSP will initialize the ECX and EDX registers to point to a temporary but writeable memory range. Register ECX points to the start of this temporary memory range and EDX points to the end of the range. The size of the temporary stack for the platform can be calculated by taking the range between ECX and EDX.

6.6 FspInitEntry

This FSP API is called after TempRamInitEntry. This FSP API initializes the memory, the CPU and the chipset to enable normal operation of these devices. This FSP API accepts a pointer to a data structure that will be platform dependent and defined for each FSP binary. This will be documented with each FSP release.

The boot loader provides a continuation function as a parameter when calling FspInit. After FspInit completes its execution, it does not return to the boot loader from where it was called, but instead returns control to the boot loader by calling the continuation function. As described in FSP header, the FspInitEntry function Byte Offset in FSP binary is at 52.

By default, E/F Segment will be set to decode to DRAM in this API. For legacy boot loaders that require E/F Segment decode to Flash, the BCT Option “Legacy E/F Segment” should be enabled.

6.6.1 Prototype

```
typedef
FSP_STATUS
(FSPAPI *FSP_FSP_INIT) (
  INOUT  FSP_INIT_PARAMS       *FspInitParamPtr
);
```

6.6.2 Parameters

FspInitParamPtr	Address pointer to the **FSP_INIT_PARAMS** structure.

6.6.3 Related Definitions

```
typedef struct {
  VOID     *NvsBufferPtr;
  VOID     *RtBufferPtr;
  CONTINUATION_PROC   ContinuationFunc;
} FSP_INIT_PARAMS;
```

NvsBufferPtr	Pointer to the non-volatile storage data buffer.
RtBufferPtr	Pointer to the runtime data buffer.
ContinuationFunc	Pointer to a continuation function provided by the boot loader.

```
typedef VOID (* CONTINUATION_PROC)(
  IN   FSP_STATUS    Status,
  IN   VOID         *HobListPtr
);
```

Status	Status of the FSP Init API.
HobBufferPtr	Pointer to the HOB data structure defined in the PI specification.

The FSP_INIT_RT_BUFFER defined below has a pointer to a data structure called UPD Data. Refer to Section 8 for details.

The FSP_INIT_RT_BUFFER contains a pointer to the Azalia configuration settings and verb tables for audio initialization. If Azalia is disabled or if the boot loader will initialize the codecs on the system board, this pointer should be a NULL.

If the boot loader passes the verb table array to the FSP, the whole data structure should be in flash. This is because the Azalia verb table data structure contains pointers and so cannot be relocated. When permanent memory is discovered the stack is relocated, which is the only other memory available when calling FspInit.

```
typedef struct {
  UINT32            *StackTop;
  UINT32            BootMode;
  VOID              *UpdDataRegPtr;
  UINT32             Reserved[7];
} FSP_INIT_RT_COMMON_BUFFER;

typedef struct {
  const PCH_AZALIA_CONFIG   *AzaliaConfig;
} FSP_INIT_RT_PLATFORM_BUFFER;

typedef struct {
  FSP_INIT_RT_COMMON_BUFFER           RtCommon;
  FSP_INIT_RT_PLATFORM_BUFFER    RtPlatform;
} FSP_RT_BUFFER;

typedef struct {
  UINT32        VendorDeviceId;
  UINT16        SubSystemId;
```

```
  UINT8         RevisionId;
  UINT8         FrontPanelSupport;
  UINT16        NumberOfEntries;
} HD_AUDIO_VERB_TABLE_HEADER;

  typedef struct {
  HD_AUDIO_VERB_TABLE_HEADER VerbTableHeader;
  UINT32                     *VerbTableData;
} HD_AUDIO_VERB_TABLE;
```

6.6.4 Return Values

FSP_SUCCESS	FSP execution environment was initialized successfully.
FSP_INVALID_PARAMETER	Input parameters are invalid.
FSP_UNSUPPORTED	The FSP calling conditions were not met.
FSP_DEVICE_ERROR	FSP initialization failed

6.6.5 Sample Code

```
static void ContinuationFunc (EFI_STATUS Status, void
*HobListPtr)
{
  /* Should add the necessary code here! */

  EFI_HOB_GUID_TYPE            *GuidHob;

  /* Get the Memory Configure Data HOB */
  EFI_PEI_HOB_POINTERS      mGuidHob;

  console_init ();

  mGuidHob.Raw = (UINT8 *) HobListPtr;
  while ((mGuidHob.Raw = GetNextHob (EFI_HOB_TYPE_GUID_EXTENSION,
mGuidHob.Raw)) != NULL) {
    if (CompareGuid(gEfiMemoryConfigDataGuid, mGuidHob.Guid-
>Name)) {
      break;
    }
    mGuidHob.Raw = GET_NEXT_HOB (mGuidHob);
  }
  GuidHob = (EFI_HOB_GUID_TYPE *) mGuidHob.Raw;
  ASSERT (GuidHob != NULL);
```

```
  /* Get Guid Hob Length including the Guid Hob structure */
  /* To replace macro GET_HOB_LENGTH (GuidHob) */
  uint32_t            GuidHobLength;
  GuidHobLength = (uint32_t) ((EFI_HOB_GENERIC_HEADER *)
&(((EFI_HOB_GUID_TYPE *)GuidHob)->Header))->HobLength;

  /* DEBUG INFO */
  printk(BIOS_DEBUG, "Memory Configure Data Hob at 0x%x (size =
0x%x).\n", (uint32_t)GuidHob, (uint32_t)GuidHobLength);

#if CONFIG_EARLY_CBMEM_INIT
  struct mrc_data_container *mrcdata;
  int output_len = ALIGN(GuidHobLength, 16);

  /* Save the MRC S3/Fastboot/ADR restore data to cbmem */
  cbmem_initialize();
  mrcdata = cbmem_add
      (CBMEM_ID_MRCDATA,
      output_len + sizeof(struct mrc_data_container));

  printk(BIOS_DEBUG, "Relocate MRC DATA from %p to %p (%u
bytes)\n",
      (EFI_HOB_GUID_TYPE *)GuidHob, mrcdata, output_len);

  mrcdata->mrc_signature = MRC_DATA_SIGNATURE;
  mrcdata->mrc_data_size = output_len;
  mrcdata->reserved = 0;

ContinuationFunc */
  while (1);
}
```

6.6.6 Description

One important piece of data that will be part of the FSP_INIT_PARAMS struct that RtBufferPtr points to will be the "StackTop." This passes the address of the stack top where the boot loader wants to establish the stack after memory is initialized and available for use.

ContinuationFunc is a function entry point that will be jumped to at the end of the FspInit() to transfer control back to the boot loader.

Please note this FspInit API initializes the permanent memory and switches the stack from the temporary memory to the permanent memory as specified by StackTop. Sometimes switching the stack in a function can cause some unexpected execution results because the compiler is not aware of the stack change during runtime and the precompiled code may still refer to the old stack for data and pointers. A stack switch therefore requires assembly code to go patch the data for the new stack location which may lead to compatibility issues. To avoid such possible compatibility issues introduced by different compilers and to ease the integration of FSP with a boot loader, the API uses the “ContinuationFunction” parameter to continue the boot loader execution flow rather than return as a normal C function. Although this API is called as a normal C function, it never returns.

The FSP needs to get some parameters from the boot loader when it is initializing the silicon. These parameters are passed from the boot loader to the FSP through the RtBuffer structure pointer.

A set of parameters that the FSP may need to initialize memory under special circumstances such as during an S3 resume and during fast boot mode are returned by the FSP to the boot loader during a normal boot. The boot loader is expected to store these parameters in a non-volatile memory such as SPI flash and return a pointer to this structure (through NvsBufferPtr) when it is requesting the FSP to initialize the silicon under these special circumstances.

During execution the FSP builds a series of data structures containing information useful to the boot loader, such as information on system memory.

This API should be called only once after the TempRamInit API.

6.7 NotifyPhaseEntry

This FSP API is used to notify the FSP about the different phases in the boot process. This allows the FSP to take appropriate actions as needed during different initialization phases. The phases will be platform dependent and will be documented with the FSP release. Examples of boot phases include “post pci enumeration” and “ready to boot”.

The FSP will lock the configuration registers to enhance security as required by the BWG when it is notified that the boot loader is ready to transfer control to the operating system.

6.7.1 Prototype

```
typedef
FSP_STATUS
(FSPAPI *FSP_NOTFY_PHASE) (
  IN  NOTIFY_PHASE_PARAMS       *NotifyPhaseParamPtr
);
```

6.7.2 Parameters

NotifyPhaseParamPtr Address pointer to the **NOTIFY_PHASE_PRAMS**

6.7.2.1 Related Definitions

```
typedef enum {
  EnumInitPhaseAfterPciEnumeration = 0x20,
  EnumInitPhaseReadyToBoot = 0x40
} FSP_INIT_PHASE;

typedef struct {
  FSP_INIT_PHASE    Phase;
} NOTIFY_PHASE_PARAMS;
```

EnumInitPhaseAfterPciEnumeration

This stage is notified when the boot loader completed the PCI enumeration and the resource allocation for the PCI devices is complete. FSP will use it to do some specific initialization for processor and chipset that requires PCI resource assignment.

EnumInitPhaseReadyToBoot

This stage is notified just before the boot loader hands off to the OS loader. FSP will use it to do some specific initialization for processor and chipset that is required before control is transferred to the OS.

6.7.3 Return Values

FSP_SUCCESS	The notification was handled successfully.
FSP_UNSUPPORTED	The notification was not called in the proper order.
FSP_INVALID_PARAMETER	The notification code is invalid.

7 FSP Output

The FSP builds a series of data structures called the Hand-Off-Blocks (HOBs) as it progresses through initializing the silicon. These data structures conform to the HOB format as described in the Platform Initialization (PI) specification - Volume 3: Shared Architectural Elements specification and can be downloaded from http://www.uefi.org/specs/

The user of the FSP binary is strongly encouraged to go through the specification mentioned above to understand the HOB design details and create a simple infrastructure to parse the HOBs, because the same infrastructure can be reused with different FSP across different platforms

It's left to the boot loader developer to decide on how to consume the information passed through the HOBs produced by the FSP. For example, even the specification mentioned above describes about 9 different HOBs; most of this information may not be relevant to a particular boot loader. For example, a boot loader design may be interested only in knowing the amount of memory populated and may not care about any other information.

The section below describes the GUID HOBs that are produced by the FSP. GUID HOB structures are non-architectural in the sense that the structure of the HOB needs is not defined in the HOB specifications. So the GUID and the data structure are documented below to enable the boot loader to consume these HOB data.

Please refer to the specification for details about the HOBs described in the *Platform Initialization (PI) specification - Volume 3: Shared Architectural Elements* specification.

7.1 Boot Loader Temporary Memory Data HOB

As described in the FspInit API, the system memory is initialized and the whole temporary memory is destroyed during this API call. However, the sub region of the temporary memory returned in the TempRamInit API may still contain boot loader-specific data which might be useful for the boot loader even after the FspInit call. So before destroying the temporary memory, all contents in this sub region will be migrated to the permanment memory, FSP builds a boot loader temporary memory data HOB and the boot loader can use it to access the data saved in the temporary memory after FspInit API if necessary. If the boot loader does not care about the previous data, this HOB can be simply ignored.

This HOB follows the **EFI_HOB_GUID_TYPE** format with the name GUID defined as below:

```
#define FSP_BOOTLOADER_TEMPORARY_MEMORY_HOB_GUID \

{ 0xbbcff46c, 0xc8d3, 0x4113, { 0x89, 0x85, 0xb9, 0xd4, 0xf3,
0xb3, 0xf6, 0x4e } };
```

7.2 FSP Reserved Memory Resource Descriptor HOB

The FSP reserves some memory for its internal use and a descriptor for this memory region used by the FSP is passed back though a HOB. This is a Generic Resource HOB, but the owner field of the HOB identifies the owner as FSP.

```
#define FSP_HOB_RESOURCE_OWNER_FSP GUID \

{ 0x69a79759, 0x1373, 0x4367, { 0xa6, 0xc4, 0xc7, 0xf5, 0x9e,
0xfd, 0x98, 0x6e } }
```

7.3 Non-Volatile Storage HOB

```
#define FSP_NON_VOLATILE_STORAGE_HOB_GUID \

{ 0x721acf02, 0x4d77, 0x4c2a, { 0xb3, 0xdc, 0x27, 0xb, 0x7b,
0xa9, 0xe4, 0xb0 } }
```

The Non-Volatile Storage (NVS) HOB provides a mechanism for FSP to request the boot loader to save the platform configuration data into non-volatile storage so that it can be reused in many cases, such as S3 resume.

The boot loader needs to parse the HOB list to see if such a GUID HOB exists after returning from the FspInit() API. If so, the boot loader should extract the data portion from the HOB, and then save it into a platform-specific NVS device, such as flash, EEPROM, etc. On the following boot flow the boot loader should load the data block back from the NVS device to temporary memory and populate the buffer pointer into FSP_INIT_PARAMS.NvsBufferPtr field before calling into the FspInit() API. If the NVS device is memory mapped, the boot loader can initialize the buffer pointer directly to the buffer.

  }
}
```

7.5 Hob Infrastructure Sample Code

Please refer to the Appendix - A for sample code.

8 FSP Configuration Firmware File

The FSP binary contains a configurable data region which will be used by the FSP during the initialization. The configurable data region has two sets of data

VPD – Vital Product Data, which can be configured statically

UPD – Updatable Product Data, which can be configured statically for default values, but also can be overridden during boot.

Both the VPD and the UPD parameters can be statically customized using a separate tool called the Binary Configuration Tool as explained in the tools section. The tool will use a Binary Setting File (BSF) to understand the layout of the configuration region within the FSP.

In addition to static configuration, the UPD data can be overridden by the boot loader during runtime. The UPD data is organized as a structure. The FspInit API parameter includes a pointer which can be initialized to point to the UPD data structure. If this pointer is initialized to NULL when calling the FspInit API, the FSP will use the default UPD data that is available in the FSP configuration region. However, if the boot loader wishes to override any of the UPD parameters, it has to copy the UPD structure to memory, override the parameters and initialize the pointer in the FspInit API input parameter to the address of the UPD structure with updated data in memory and call FspInit API. The FSP will use this data structure instead of the default configuration region data.

When calling the FspInit API, the stack is in temporary RAM where the UPD data structure is copied, updated, and passed to the FSP API. When permanent memory is initialized, the FSP will set up a new stack in the permanent memory. However, the FSP will save the stack that was in the Temporary Memory in a HOB. If the boot loader wishes to refer to the modified UPD Data, it can be done by parsing the HOB which has the Temporary Stack's data.

Both the VPD and the UPD structure definition is provided below. As mentioned above, to update these configuration regions statically using the Binary Configuration Tool, a BSF file will be provided separately.

```
typedef struct _UPD_DATA_REGION {
  UINT64   Signature;                    /* Offset 0x0000 */
  UINT64   Reserved;                     /* Offset 0x0008 */

```

9 Tools

A Binary Configuration Tool (BCT) will be provided with the FSP binary that can used on the FSP binary to allow a user to modify certain well defined configuration values in the FSP binary. The BCT will typically provide a graphical user interface (GUI). The Binary Configuration Tool (BCT) will be provided with separate documentation that explains the usage of the tool.

10 Other Host Boot Loader Concerns

10.1 Power Management

Intel® FSP does not provide power management functions besides making power management features available to the host boot loader. ACPI is an independent component of the boot loader, and it will not be included in Intel® FSP.

10.2 Bus Enumeration

Intel® FSP will initialize the CPU and the companion chips to a state that all bus topology can be discovered by the host boot loader.

10.3 Security

Intel® FSP does not support secure boot mechanism as it is not supported by the Minnow SOC.

10.4 64-bit Long Mode

Intel® FSP operates in 32-bit mode; it is the responsibility of the host boot loader to transition to 64-bit Long Mode if desired.

10.5 Pre-OS Graphics

Intel® FSP does not include graphics initialization function. For pre-OS graphics initialization solutions, please contact your Intel representative.

Appendix A – HOB Parsing Sample Code

The sample code provided here was derived from the EDK2 source available for download at

http://sourceforge.net/apps/mediawiki/tianocore/index.php?title=EDK2

Appendix B – Sample Code to Find FSP Header

The sample code provided below parses the FSP binary and finds the address of the FSP Header within it.

As the FV parsing has to be done before stack is available, a mix of assembly language code and C code is used. The C code is used to parse the data structures and find the FSP INFO Header. However, since the compiler will add prolog or epilog code to the C function, inline assembly is used to bypass those portions of the C code.

The sample code provided here uses header files derived from the EDK2 source available for download at

http://sourceforge.net/apps/mediawiki/tianocore/index.php?title=EDK2

```
#include "PiFirmwareVolume.h"
#include "PiFirmwareFile.h"

void __attribute__((optimize("O0"))) find_fsp_entry_func ()
{
  volatile register UINT8 *ptr asm ("eax");

  //
  // This label will be called directly using a
  // ROM based stack since the temporary memory is not available
  // yet. In order to make it work, C function prologue has to be
  // skipped and only register variable can be used.
  // EAX needs to point to the FSP base address before the call.
  // On return, the EAX will point to the FSP INFO header if
  // successful.If mulitple FVs are used for the FSP, the EAX
  // should point to the FV base address and this function will
  // try to locate the FSP INFO header inside this FV. On return,
  // the EAX will point to the FSP INFO header inside the boot FV
  // if the header is found and valid. Otherwise, NULL will be
  // returned in EAX.
  //
  __asm__ __volatile__ (
      ".global find_fsp_entry\n\t"
      "find_fsp_entry:\n\t"
    );

  //
  // Validate FV signature _FVH
  //

  if (((EFI_FIRMWARE_VOLUME_HEADER *)ptr)-> Signature !=
0x4856465F) {
    ptr = 0;
```

```
    goto NotFound;
  }

  //
  // Add the Ext Header size to the Ext Header base to go to the
  // end of FV header
  //
  ptr += ((EFI_FIRMWARE_VOLUME_HEADER *)ptr)->ExtHeaderOffset;
  ptr += ((EFI_FIRMWARE_VOLUME_EXT_HEADER *)ptr)->ExtHeaderSize;

  //
  // Align the end of FV header address to 8 bytes
  //
  ptr  = (UINT8 *)(((UINT32)ptr + 7) & 0xFFFFFFF8);

  //
  // Now ptr is pointing to thr FFS Header. Verify if the GUID
  // matches the FSP_INFO_HEADER GUID
  //
  if ( (((UINT32 *)&(((EFI_FFS_FILE_HEADER *)ptr)->Name))[0] !=
0x912740BE) ||
       (((UINT32 *)&(((EFI_FFS_FILE_HEADER *)ptr)->Name))[1] !=
0x47342284) ||
       (((UINT32 *)&(((EFI_FFS_FILE_HEADER *)ptr)->Name))[2] !=
0xB08471B9) ||
       (((UINT32 *)&(((EFI_FFS_FILE_HEADER *)ptr)->Name))[3] !=
0x0C3F3527) ) {
      ptr = 0;
      goto NotFound;
  }

  //
  // Add the FFS Header size to the base to find the Raw section
  // Header
  //
  ptr += sizeof(EFI_FFS_FILE_HEADER);
  if (((EFI_RAW_SECTION *)ptr)->Type != EFI_SECTION_RAW) {
      ptr = 0;
      goto NotFound;
  }

  //
  // Add the Raw Header size to the base to find the FSP INFO
  // Header
  //
  ptr += sizeof(EFI_RAW_SECTION);

NotFound:
  __asm__ __volatile__ ("ret");

}
```

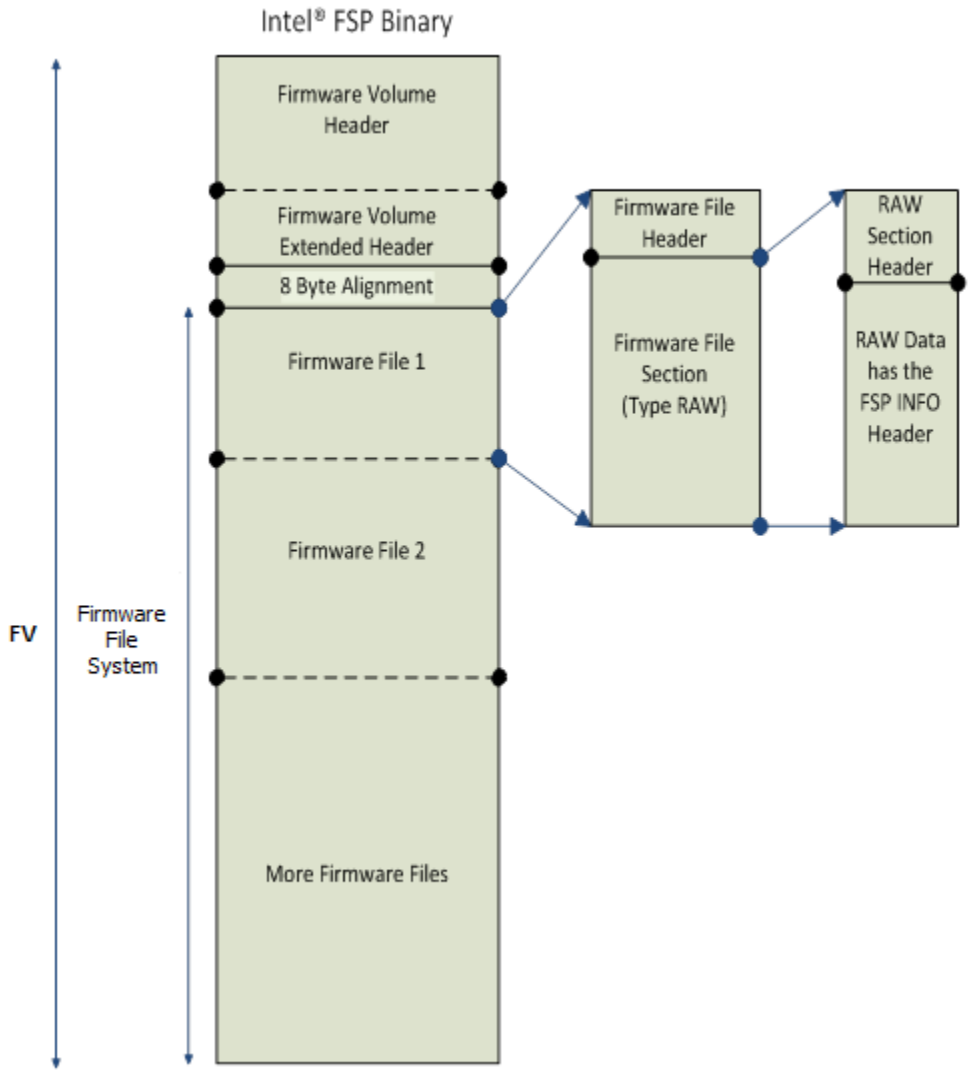
Now, call this function using a temporary ROM stack containing the return address and bypass the prolog or epilog code of the C function like below.

```
  lea   findFspHeaderStack, %esp
  jmp   find_fsp_entry

findFspHeaderStack:
 .align 4
 .long  findFspHeaderDone

findFspHeaderDone:
```

A pictorial representation of the data structures that we parse in the above code is given below.



Intel® FSP Binary
Firmware Volume Header
Firmware Volume Extended Header
8 Byte Alignment
Firmware File 1
Firmware File 2
More Firmware Files
FV
Firmware File System
Firmware File Header
Firmware File Section (Type RAW)
RAW Section Header
RAW Data has the FSP INFO Header
